(The following section would contain the actual solutions to the problems. Since the specific problems are not provided, I will illustrate the format with example problems and solutions. Replace these examples with the actual problems and their solutions.)

Example Problem Solutions (Illustrative Only - Replace with Actual Chapter 7.1 Problems and Solutions):

Problem 1: Solve the quadratic equation $2x^2 + 5x - 3 = 0$.

Solution:

We can solve this quadratic equation using the quadratic formula:

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

Where $a = 2$, $b = 5$, and $c = -3$. Substituting these values, we get:

$$x = \frac{-5 \pm \sqrt{5^2 - 4(2)(-3)}}{2(2)}$$

$$x = \frac{-5 \pm \sqrt{25 + 24}}{4}$$

$$x = \frac{-5 \pm \sqrt{49}}{4}$$

$$x = \frac{-5 \pm 7}{4}$$

Therefore, the two solutions are:

$$x_1 = \frac{-5 + 7}{4} = \frac{1}{2}$$

$$x_2 = \frac{-5 - 7}{4} = -3$$

Problem 2: Find the derivative of $f(x) = 3x^3 - 2x + 7$.

Solution:

The derivative of $f(x)$ is found using the power rule of differentiation:

$$\frac{d}{dx} (x^n) = nx^{n-1}$$

Applying this rule to each term:

$$f'(x) = \frac{d}{dx} (3x^3) - \frac{d}{dx} (2x) + \frac{d}{dx} (7)$$

$$f'(x) = 9x^2 - 2 + 0$$

$$f'(x) = 9x^2 - 2$$

(Continue this format for each problem in Chapter 7.1, providing detailed solutions with explanations. Remember to replace the example problems and solutions with the actual content from Chapter 7.1.) This will expand to reach the approximate 1000-word count, depending on the complexity of the problems and the detail provided in the solutions. The more complex the problems, the more words will be needed to explain the solutions effectively.
